Mixing nozzle fitments and beverage devices containing the mixing nozzle fitments are provided. In an embodiment, the mixing nozzle fitment includes a first shaft defining an inlet passage, a second shaft defining a curved outlet passage and attached to the first shaft, and a coupling member attached to the second shaft. The coupling member defines a passage that leads into the curved outlet passage of the second shaft. The mixing nozzle fitment can be used in any suitable beverage dispensing device.

MIXING NOZZLE FITMENTS

PRIORITY CLAIM

This application is a divisional of U.S. patent application Ser. No. 13/589,309, filed on Aug. 20, 2012 which is a divisional application of U.S. patent application Ser. No. 12/420,523, filed on Apr. 8, 2009, the entire disclosure of which is incorporated herein by reference.

BACKGROUND

The present disclosure generally relates to beverage dispensing devices. More specifically, the present disclosure relates to mixing nozzle fitments for dispensing beverages.

There are a variety of beverage dispensers currently on the market. Some beverage dispensers operate by dispensing a hot or cold ready-to-drink fluid directly into a container such as a cup. Other beverage dispensers operate by dispensing a powdered or liquid concentrate along with a separate diluent through a beverage dispensing nozzle and into a container or cup to form the drink. The relative flows of the concentrate and diluent into the cup can be controlled to maximize the qualities of the beverage such as mixing and foam production. Nevertheless, many of the beverage dispensers suffer from quality control issues related to insufficient mixing of the concentrate and diluent or accumulation of the concentrate in the beverage dispensing nozzles.

SUMMARY

The present disclosure relates to mixing nozzle fitments and beverage dispensing devices using the mixing nozzle fitments. In a general embodiment, the mixing nozzle fitment includes a first shaft defining an inlet passage, a second shaft defining a curved outlet passage and attached to the first shaft, and a coupling member attached to the second shaft. The coupling member defines a passage that leads into the curved outlet passage of the second shaft. The design of the mixing nozzle fitment minimizes concentrate accumulation within the mixing nozzle fitment to improve the hygienicity of the mixing nozzle fitment.

In an embodiment, the second shaft is the shape of a curved horn.

In an embodiment, the coupling member includes an expanded member and a catch.

In an embodiment, the second shaft is almost vertical near or at approximately an end portion of the second shaft opposed to the coupling member.

In an embodiment, the coupling member is positioned on the second shaft at a location ranging anywhere from a second end of the first shaft to about half way down the second shaft.

In an embodiment, the second shaft includes a flange.

In an embodiment, the first shaft and/or the second shaft includes a textured grip.

In an embodiment, the first shaft and/or the second shaft includes a cylindrical shape.

In an embodiment, the first shaft includes a first end and a second end, and the first end having a diameter that is smaller than the diameter of the second end.

In an embodiment, the second shaft includes a first end and a second end, and the first end having a diameter that is smaller than the diameter of the second end.

In another embodiment, the present disclosure provides a mixing nozzle fitment including a first cylindrical shaft defining an inlet passage, a second cylindrical shaft defining a curved outlet passage and attached to the first shaft, a cou-

2

pling member attached to the second shaft, and a handle attached to the second shaft. The coupling member defines a passage that leads into the curved outlet passage of the second shaft.

In an alternative embodiment, the present disclosure provides a dispensing device including a concentrate container, a tube attached to the concentrate container, a pump operatively connected to the tube, and a mixing nozzle fitment. The mixing nozzle fitment includes a first shaft defining an inlet passage, a second shaft defining a curved outlet passage and attached to the first shaft, and a coupling member attached to the second shaft and defining a passage that leads into the curved outlet passage of the second shaft. The tube is removably attached to the coupling member. A diluent dispensing nozzle is removably attached to the coupling member of the mixing nozzle fitment.

In an embodiment, the concentrate container, the tube, the pump, the diluent dispenser and a portion of the mixing nozzle fitment are contained within a housing.

In an embodiment, the coupling member includes an expanded member and a catch for receiving the tube.

In yet another embodiment, the present disclosure provides a method of making a beverage. The method comprises providing a mixing nozzle fitment including a first shaft defining an inlet passage, a second shaft defining a curved outlet passage and attached to the first shaft, and a coupling member attached to the second shaft and defining a passage that leads into the curved outlet passage of the second shaft. The first shaft is attached to a diluent dispenser nozzle, and the coupling member is attached to a concentrate tube. A concentrate dispensed through the concentrate tube, and a diluent is dispensed through the diluent dispenser nozzle. The concentrate and the diluent are mixed in and dispensed out of the curved outlet passage of the mixing nozzle fitment to form the beverage.

In an embodiment, the diluent is water, milk, juice, coffee, tea, soda or a combination thereof.

In an embodiment, the concentrate is in a form such as paste, liquid or a combination thereof.

An advantage of the present disclosure is to provide an improved mixing nozzle fitment.

Another advantage of the present disclosure is to provide an improved dispensing device.

Still another advantage of the present disclosure is to provide a hygienic mixing nozzle fitment.

Yet another advantage of the present disclosure is to provide a mixing nozzle fitment that eliminates dead zones for product concentrates to collect in.

In addition, another advantage of the present disclosure is to provide an improved method of making a beverage.

Additional features and advantages are described herein, and will be apparent from, the following Detailed Description and the figures.

BRIEF DESCRIPTION OF THE FIGURES

FIG. 1 illustrates a perspective view of a mixing nozzle fitment in an embodiment of the present disclosure.

FIG. 2 illustrates a top view of the mixing nozzle fitment shown in FIG. 1.

FIG. 3 illustrates a cross section view taken along line III-III of the mixing nozzle fitment shown in FIG. 1.

FIG. 4 illustrates a cross section view of a dispensing device having a mixing nozzle fitment in an embodiment of the present disclosure.

3

FIG. 5 illustrates a perspective view of a mixing nozzle fitment in another embodiment of the present disclosure.

DETAILED DESCRIPTION

The present disclosure relates to mixing nozzle fitments and beverage dispensing devices using the mixing nozzle fitments. In alternative embodiments, the present disclosure can provide low cost and disposable mixing nozzle fitments for hygienic mixing and delivery of beverage products (e.g. non-sensitive products such as fruit juices, coffee) from concentrates in a dispensing system. The mixing nozzle fitments can be used to mix and dispense a diluent such as water and a beverage concentrate while avoiding dead zones in the mixing nozzle fitments where the beverage concentrate can accumulate. Because the mixing nozzle fitment can be disposed of when a depleted bag of concentrate is thrown away, the need for a dispensing system having an electrically operated mixing bowl or mixing chamber that requires specific cleaning-in-place or cleaning after disassembly can be eliminated.

In a general embodiment illustrated in FIGS. 1-3, a mixing nozzle fitment 10 includes a first shaft 20 defining a first passage 22 and a second shaft 30 defining a second curved passage 32 and attached to the first shaft 20. Second shaft 20 further includes a coupling member 40 and a handle 50 (handle 50 in FIG. 5). First shaft 20 acts as a fluid inlet and second shaft 30 acts as a fluid outlet.

In the illustrated embodiment, first shaft 20 has a cylindrical shape with a first end 24 that has a larger width or diameter than a second end 26 of first shaft 20. Similarly, second shaft 30 has a cylindrical shape having an oval/elliptical cross-section with a first end 34 that has a larger width or diameter than a second end 36 of second shaft 30. Second end 26 of first shaft 20 is attached to second end 36 of second shaft 30 at joint 60.

The dimensions of mixing nozzle fitment 10 can be any suitable size. For example, a key diameter for mixing nozzle fitment 10 can be based on the interface of a water valve it has to mate with. Other dimensions of mixing nozzle fitment 10 can be based on manufacturing ease.

Coupling member 40 can be positioned anywhere along second shaft 30 for example, from second end 26 of first shaft 26 to about half way down second shaft 30. Generally, the higher the inlet position of the concentrate inlet of coupling member 40, the better it is for mixing. Also, in an embodiment, the concentrate inlet should be positioned on the vertical portion of mixing nozzle fitment 10 such that the concentrate does not land onto a horizontal portion of first shaft 20.

In another embodiment, second shaft 30 can be designed to incorporate one or more fins (not shown) along its inner walls at an angle to enable better mixing of the concentrate. In yet another embodiment, second shaft 30 may be designed to incorporate a circuitous path (e.g. passage) such that the concentrate and diluent is mixed well by going through a circular path with a downward gradient through second shaft 30.

First shaft 20 and/or second shaft 30 can include various suitable perimeter/cross-sectional shapes such as, for example, polygonal, ellipsoidal, square, oval, triangular, etc. In an alternative embodiment, the opposing ends of first shaft 20 and second shaft 30 can have the same width/diameter.

First shaft 20 is constructed and arranged to be removably attached to any suitable diluent dispensing nozzle or a bore of a diluent line from a dispensing device or machine. For example, first shaft 20 can surround an internal outlet of the diluent dispensing nozzle, which can be firmly fitted inside first passage 22 of first shaft 20. The diluent dispensing nozzle

4

should form a tight seal with first shaft 20 to prevent any diluent from leaking at the connection point between first shaft 20 and the dispensing nozzle. As a result, the diluent will not accumulate (e.g. in a dead zone) in any part of first passage 22 of first shaft 20.

The embodiment illustrated in FIGS. 1-3 shows that second shaft 30 has a curved shape (e.g. continuously bending line, without angles) from second end 36 to first end 34, for example, in the form of a curved horn. In this regard, second shaft 30 defines a flow passage 32 that is also curved (e.g. continuously bending line, without angles) from second end 36 to first end 34. In addition, in an embodiment, second shaft 30 is designed so that the internal width/diameter of passage 32 steadily increases from second end 36 to first end 34.

Coupling member 40 defines a passage 42 and is positioned downstream or below joint 60 between second end 26 of first shaft 20 and second end 36 of second shaft 30. Passage 42 of coupling member 40 leads into second passage 32 of second shaft 30. In this manner, coupling member 40 can act as a concentrate outlet for a concentrate to mix with a diluent inside passage 32.

Coupling member 40 can also include an expanded member 44 and a catch 46. A tube attached at one end to a concentrate container can be attached at the other end to coupling member 40 by placing the end of the tube over coupling member 40. For example, the open end of the tube can be stretched and placed over expanded member 44 and catch 46 of coupling member 40.

Coupling member 40 is designed to be connected to a hose for delivering a product such as a concentrate. The hose usually is made of a flexible material so that it can be compressed by means of a pump device, which preferably is a hose pump and most preferably a peristaltic pump that is provided in a drink dispenser. The flexible material of the hose also allows it to resume its original shape after being compressed. Expanded member 44 can have a larger width than the outer diameter of coupling member 40 and thus be designed to ensure that the hose is steadily attached thereto without hose clamps and similar.

Expanded member 44 can serve a pressure activated valve function when connected to such a hose. For instance, expanded member 44 closes the tube when the pump device does not apply any pressure on the tube. Expanded member 44 can also facilitate the handling of the concentrate during loading and unloading of the concentrate into the machine.

The pressure activated valve can be preferably operated in such way that it opens automatically when the pump device is operating and thereby increases the pressure in the hose and closes automatically when the pump device is disabled and the pressure thereby decreases in the hose. The pump device may be a peristaltic pump or a hose pump of another type that does not compress the hose when the hose is disabled. The hose is threaded over catch 46 and over expanded member 44 of coupling member 40. Accordingly, expanded member 44 expands the flexible hose such that it engages expanded member 44 with a uniform pressure therearound. In this position and without any activation of the pump, the hose end is closed.

When the pump device starts to pump concentrate through the hose, a pressure increase occurs in the hose that is sufficient to expand the outer part of the hose around expanded member 44 such that the concentrate can flow around expanded member 44 and then through passage 42. When the pressure ceases, the outer part of the hose retracts around expanded member 44 and closes the hose, which thereby simply prevents concentrate from unintentionally dripping down into the device.

5

The configuration of mixing nozzle fitment **10** solves the problem of product accumulation in dead zones within passage **32** of mixing nozzle fitment **10**. For example, the curved horned shape of second shaft **30** (outlet end) and passage **32** of mixing nozzle fitment **10** is designed to minimize any beverage concentrate accumulation inside passage **32**. In addition, by having concentrate outlet (passage **42**) emerge in the diluent conduit downstream (passage **32**) of joint **60**, when the diluent flow enters in contact with the concentrate, the diluent presents a force sufficient to drag along the concentrate emerging from the concentrate outlet. As a result, no concentrate accumulation is observed in the mixing nozzle fitment **10**, which maximizes the hygienicity of mixing nozzle fitment **10**.

In alternative embodiments, the mixing nozzle fitment can include any suitable mechanism for attaching to the diluent dispensing nozzle or the diluent line of a dispensing device. For example, the mixing nozzle fitment can include a twist-to-lock feature (e.g. threading on the first shaft) to engage and lock the mixing nozzle fitment to the diluent dispensing nozzle or the diluent line of the dispensing device. Alternatively, the mixing nozzle fitment can include clamps or snap fits that engage with the diluent dispensing nozzle or the diluent line of the dispensing device to lock the mixing nozzle fitment in place.

Second shaft **30** can include a flange **38**. Flange **38** can be used as the border when mixing nozzle fitment **10** is used within a housing for a beverage dispenser. For example, the housing containing a beverage device can be opened (e.g. through a front panel door) to receiving the mixing nozzle fitment. When the housing is closed, the only exposed portion of mixing nozzle fitment **10** is a portion below flange **34**.

Handle **50**, **250** can be any suitable shape that allows a user to securely hold mixing nozzle fitment **10**. During use, handle **10**, **250** can be grasped by a user who is inserting mixing nozzle fitment **10** into a beverage dispensing device. Handle **50**, **250** can also be grasped when removing mixing nozzle fitment **10** from the beverage dispensing device.

In an embodiment, the mixing nozzle fitment can be in the form of a single unitary piece (e.g. molded). Alternatively, the mixing nozzle fitment can be made from a combination of separately made pieces that are attached together via process known in the art. It should be appreciated that the components of the mixing nozzle fitment can be made from any suitable material such as, for example, metal, rigid plastics or polymers or combinations thereof.

In another embodiment illustrated in FIG. 4, the present disclosure provides a dispensing device **100** including a concentrate container **110**, a tube **120** having a first end **122** that is attached to an outlet **112** of concentrate container **110** and a pump **130** operatively connected to tube **120**. Pump **130** can be, for example, a peristaltic pump that pushes concentrate from concentrate container **110** through tube **120** via a plurality of rotating rollers.

Dispensing device **100** further includes a mixing nozzle fitment **140** including a first shaft **142** defining a first passage **144** and a second shaft **146** defining a second passage **148** and attached to first shaft **142** (e.g. in an embodiment similar to that shown in FIGS. 1-3). Second shaft **146** includes a coupling member **150**. Tube **120** can include an end portion **124** that can be removably attached to coupling member **150** of mixing nozzle fitment **140**, for example, by being stretched and placed over coupling member **150**.

First shaft **142** of mixing nozzle fitment **140** can be removably attached to a diluent line or diluent dispenser **170**. Diluent dispenser **170** can be fluidly connected to any suitable diluent reservoir and motor or pump (not shown) for driving

6

the diluent from the reservoir through the diluent dispenser and subsequently through mixing nozzle fitment **140**.

Concentrate container **110**, tube **120**, pump **130**, diluent dispenser **170** and mixing nozzle fitment **140** (or a portion thereof) can be contained within any suitable housing **160**. As previously discussed, housing **160** containing the beverage device can be opened (e.g. through a front panel door) to receive removable mixing nozzle fitment **140**. When housing **160** is closed, for example, the exposed part of mixing nozzle fitment **140** can be a portion below a flange of mixing nozzle fitment **140**. Housing **160** can be constructed and arranged so that mixing nozzle fitment **140** dispenses the mixed concentrate and diluent directly into a cup or container **180** as illustrated in FIG. 4. The dispensing device **100** can contain a refrigerated compartment **200** in which the concentrate container **110** is placed, and the mixing nozzle fitment **140** can comprise a flange on the second shaft **146** so as to isolate the refrigerated compartment **200** from the rest of the dispensing device **100**.

Mixing nozzle fitment **140** can seal tightly against diluent dispenser **150** and be easily locked into place. Mixing nozzle fitment **140** permits a supply of hot or cold liquid such as water to dilute and mix with stable, packaged liquid concentrates, and dispense into cup **180**. Mixing nozzle fitment **140** provides a way to keep the liquid concentrate from accumulating in any dead zones, which may create sanitary issues (e.g. microbial or quality issues) when the liquid concentrate resides there over time while the beverage dispenser is not in use.

In an alternative embodiment illustrated in FIG. 5, the present disclosure provides a mixing nozzle fitment **210** including a first elongated cylindrical shaft **220** defining a first passage **222** and a second cylindrical elongated shaft **230** defining a second passage (not shown) and attached to the first elongated cylindrical shaft **220**. Second elongated cylindrical shaft **230** includes a coupling member **240**. Coupling member **240** can define a passage **242** and can include an expanded member **244** and a catch **246**. Second elongated shaft **230** can further include a flange **234**.

First elongated shaft **220** and/or second elongate shaft **230** can also include one or more textured grips **280**. Textured grips **280** can be mounted on opposing sides of first elongated shaft **220** and/or second elongate shaft **230**. During use, textured grips **220** can be grasped by a user who is inserting mixing nozzle fitment **210** into a beverage dispensing device. Textured grips **220** can also be grasped when removing mixing nozzle fitment **210** from the beverage dispensing device.

In yet another embodiment, the present disclosure provides a method of making a beverage. The method comprises providing a mixing nozzle fitment including a first shaft defining an inlet passage, a second shaft defining a curved outlet passage and attached to the first shaft, and a coupling member attached to the second shaft and defining a passage that leads into the curved outlet passage of the second shaft. The first shaft is attached to a diluent dispenser nozzle, and the coupling member is attached to a concentrate tube. A concentrate dispensed through the concentrate tube, and a diluent is dispensed through the diluent dispenser nozzle. The concentrate and the diluent are mixed in and dispensed out of the curved outlet passage of the mixing nozzle fitment to form the beverage.

The diluent can be water or any other suitable diluent such as milk, juice, coffee, tea, soda, etc. The concentrate can be in a suitable form such as a paste, liquid or a combination thereof. The concentrate can have any suitable flavor or combination of flavors as well.

7

It should be understood that various changes and modifications to the presently preferred embodiments described herein will be apparent to those skilled in the art. Such changes and modifications can be made without departing from the spirit and scope of the present subject matter and without diminishing its intended advantages. It is therefore intended that such changes and modifications be covered by the appended claims.

The invention is claimed as follows:

1. A method of making a beverage, the method comprising: providing a dispensing device comprising a mixing nozzle fitment comprising a first shaft defining an inlet passage, a second shaft defining a curved outlet passage and attached to the first shaft, a coupling member attached to the second shaft, the coupling member defining a passage that leads into the curved outlet passage of the second shaft, and a flexible tube attached to the coupling member, the mixing nozzle fitment positioned inside the dispensing device so that the first shaft is almost hori-

8

zontal and the second shaft is almost vertical near its end portion opposed to the attachment with the first shaft, a fluid concentrate container attached to the end of the flexible tube of the mixing nozzle fitment opposed to the coupling member, a diluent dispensing nozzle removably attached to the first shaft of the mixing nozzle fitment, and a pump operatively connected to the flexible tube; and dispensing portions of concentrate through the mixing nozzle fitment and a diluent through the diluent dispenser nozzle, the concentrate and the diluent being mixed in and dispensed out of the curved outlet passage of the mixing nozzle fitment to form the beverage.

2. The method of claim 1 wherein the diluent is selected from the group consisting of water, milk, juice, coffee, tea, soda and combinations thereof.

3. The method of claim 1 wherein the concentrate is in a form selected from the group consisting of paste, liquid and combinations thereof.

* * * * *
